Variance and Inbreeding

Peter von Rohr
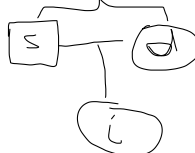

2022-11-04

Assumption

$F_i > 0$; $var(u_i)$ is increased

▶ Variance of breeding value u_i: $var(u_i) = (A)_{ii}\sigma_u^2$
▶ Diagnoal elements of numerator relationship matrix A

$F_i = \frac{1}{2}(A)_{sd}$ $(A)_{sd}$

$$(A)_{ii} = (1 + F_i)$$

s

d

i

where

$\quad F_i \quad$ inbreeding coefficient of animal i
$\quad \sigma_u^2 \quad$ genetic additive variance

▶ The higher F_i, the higher the similarity, the higher the variance

$\rightarrow$ Contradiction?

Unrelated parents s and d ==> (A)_{sd} = 0
==> F_i = 0 ==> (A)_{ii} = 1

Variance and Inbreeding

- Relationship between variance and inbreeding
- How does inbreeding affect the genetic variance?
- How do we get inbreeding in a population?

$\rightarrow$ Population separates into different lines

Population with Inbreeding

Generation 0	Base Population (N = Infinity)			
Gametes	2N	2N	2N	2N
Generation 1	N	N	N	N
Gametes	2N	2N	2N	2N
Generation 2	N	N	N	N

Assumptions

- N individuals
- self-fertilizing, shedding constant rate of eggs and sperm
- at a given locus: alleles in base population are non-identical by descent
- N individuals produce $2N$ gametes (eggs and sperm) at constant rate
- probability that a pair of gametes taken at random carry identical alleles: $1/2N$
- probability corresponds to the **inbreeding coefficient** (F)

Inbreeding Coefficient

- In generation 1:

$$F_1 = \frac{1}{2N}$$

- second generation
  - either de-novo match of alleles or
  - the same alleles from generation 1

$$F_2 = \frac{1}{2N} + (1 - \frac{1}{2N}) * F_1$$

- new variable $\Delta F = \frac{1}{2N}$, then

$$F_2 = \Delta F + (1 - \Delta F) * F_1$$

Inbreeding Coefficient II

▶ Generation t: $F_t = \Delta F + (1 - \Delta F) * F_{t-1}$
▶ Solving for ΔF

$$\Delta F = \frac{F_t - F_{t-1}}{1 - F_{t-1}}$$

▶ Panmicitic Index $P = 1 - F$

$$\frac{P_t}{P_{t-1}} = 1 - \Delta F$$

$$P_t = (1 - \Delta F)^t * P_0 \text{ with } P_0 = 1$$

$$F_t = 1 - (1 - \Delta F)^t$$

Variance of Gene Frequency

▶ Allele frequencies (p and q) no longer constant in lines $\rightarrow$ variation

▶ Variance of change of q (same for p)

$$\sigma^2_{\Delta q} = \frac{p_0 q_0}{2N} = p_0 q_0 \Delta F$$

▶ Variance of q (same for p)

$$\sigma^2_q = p_0 q_0 F$$

Genotype Frequencies

▶ Average genotype frequency of homozygotes across all lines: $\bar{q^2}$

▶ Definition of variance

$$\sigma_q^2 = \bar{q^2} - \bar{q}^2$$

where $\bar{q}$ is the mean allele frequency across all lines and hence is the same as q_0 in the base population

▶ Therefore

$$\bar{q^2} = q_0^2 + \sigma_q^2 = q_0^2 + p_0 q_0 F$$

Genotype Frequencies II

Table 1: Genotype Frequencies for a bi-allelic locus, expressed in terms of inbreeding coefficient F

Genotype	Original Frequencies	Changes due to inbreeding
$A_1 A_1$	p_0^2	$+p_0 q_0 F$
$A_1 A_2$	$2 p_0 q_0$	$-2 p_0 q_0 F$
$A_2 A_2$	q_0^2	$+p_0 q_0 F$

Changes of Mean Value

Table 2: Derivation of Inbreeding Depression

Genotype	Frequency	Value	Product
A_1A_1	$\bar{p}^2 + \bar{p}\bar{q}F$	a	$(\bar{p}^2 + \bar{p}\bar{q}F)a$
A_1A_2	$2\bar{p}\bar{q} - 2\bar{p}\bar{q}F$	d	$(2\bar{p}\bar{q} - 2\bar{p}\bar{q}F)d$
A_2A_2	$\bar{q}^2 + \bar{p}\bar{q}F$	$-a$	$-(\bar{q}^2 + \bar{p}\bar{q}F)a$

Inbreeding Depression

$$M_F = (\bar{p}^2 + \bar{p}\bar{q}F)a + (2\bar{p}\bar{q} - 2\bar{p}\bar{q}F)d - (\bar{q}^2 + \bar{p}\bar{q}F)a$$
$$= a(\bar{p} - \bar{q}) + 2d\bar{p}\bar{q} - 2d\bar{p}\bar{q}F$$
$$= a(\bar{p} - \bar{q}) + 2d\bar{p}\bar{q}(1 - F)$$
$$= M_0 - 2d\bar{p}\bar{q}F$$

Changes of Variance

- Only additive locus
- Within line: as before

$$V_{\tilde{G}} = 2(\bar{p}q)a^2$$
$$= 2p_0 q_0 (1 - F)$$
$$= V_G (1 - F)$$

- New variance component: between line

$$var(M) = \sigma_M^2 = 4a^2 \sigma_q^2 = 4a^2 p_0 q_0 F = 2F V_G$$

Summary

Table 3: Partitioning of the variance in a population with inbreeding coefficient F

Source	Variance
Between lines	$2FV_G$
Within lines	$(1 - F)V_G$
Total	$(1 + F)V_G$
